

Share of Youth Aged 11 to 17 in New Mexico with Depression (NSCH) 2016–2024

Source: United States Census Bureau, 2016–2024 National Survey of Children’s Health (“NSCH”) survey responses for New Mexico 11–17-year-olds

Note: This chart shows the share of parents who responded to the following NSCH questions “Has a doctor or other health care provider EVER told you that this child has [d]epression?” with “Yes,” “If yes, does this child CURRENTLY have the condition?” with “Yes,” and “If yes, is it Mild[,], Moderate[, or] Severe?” with “Moderate” or “Severe.” The NSCH is an annual nationally representative survey of children between 0–17 years of age. Responses have been restricted to 11–17-year-olds and to the state of New Mexico. The NSCH is also representative for New Mexico. Non-responses to the charted question have been excluded. To extrapolate the shares in the survey sample to the population of New Mexico, responses are multiplied by respondent weights provided by the U.S. Department of Health and Human Services for the NSCH data to estimate the share of individuals experiencing depression in New Mexico. These respondent weights account for demographic and socio-economic differences between the sample and population estimates and ensure that the weighted totals of respondents in the survey match populations estimates by age group, ethnicity, sex, and household characteristics. Responses are weighted by the following age groups: 0–5, 6–11, 12–17 years old. Weighting has not been further adjusted to account for age filtering to 11–17-year-olds as the survey results do not provide specific weights for this subgroup.
